

AMENDMENT TO THE SPECIFICATION (Page 7)

As will be apparent, and because of this difference in
5 respective diameters, the header pipes 20, 22, 24 and 26 are each
able to slide within the collector pipes 80, 82, 84 and 86, in
easing their respective insertions and in facilitating their
respective removals, one from another. Thus, when imagining the
rotation of the collector 18 inwardly of the plane of the paper
10 and to the right of the position shown in FIGURE 2, one arrives at
the orientation shown in FIGURE 3, wherein the header pipe 24
would be oriented to slide within the upper-left aperture 72
(where collector pipe 80 is secured), while the header pipe 20
would be oriented to slide within the upper right aperture 74
15 (where collector pipe 82 is secured). In like manner, and with
this rotation and orientation, the header pipe 26 would be
oriented to slide within the lower-left aperture 76 (where
collector pipe 84 is secured), and header pipe 22 would be
oriented to slide within the lower-right aperture 78 (where
20 collector pipe 86 is secured). As will be appreciated, because of
the clearance of the header pipes with the collector pipes where
they are coupled together, it becomes then but a simple matter to
slidably remove the header pipe from its respective header
collector input pipe, and to then adjust the header pipe out-of-
25 the-way when it is desired to service the various components, sys-
tems and/or assemblies of the vehicle previously obstructed from
